**خلاصه مقاله:**

Abstract Relativistic ion-acoustic waves are investigated in an electronegative plasma. The use of the reductive perturbation method summarizes the hydrodynamic model to a nonlinear Schrödinger equation which supports the occurrence of modulational instability (MI). From the MI criterion, we derive a critical value for the relativistic parameter  $\alpha$ , below which MI may develop in the system. The MI analysis is then conducted considering the presence and absence of negative ions, coupled to effects of relativistic parameter and the electron-to-negative ion temperature ratio. Under high values of the latter, additional regions of instability are detected, and their spatial expansion is very sensitive to the change in  $\alpha$ . The parametric analysis of super-rogue wave amplitude is performed, where its enhancement is debated relatively to changes in  $\alpha$ . The link between the enhancement of the rogue wave amplitude and the presence/absence of negative ions is discussed. The results show that the enhancement of the rogue wave amplitude is more pronounced in the presence of negative ions.
