خلاصه مقاله:

Background: The carcinoma of ectopic breast tissue represents a rare condition. The ectopic glandular tissue is frequently located in the axilla, so ectopic breast lesions must be distinguished from other subcutaneous masses arising in this location. Case presentation: We describe the case of a ۷۵-year-old woman presented to our department for the recent manifestation of an axillary cutaneous lesion. She underwent mammogram, breast ultrasound, fine-needle aspiration cytology, breast magnetic resonance imaging, thoraco-abdominal computed-tomography scan and punch biopsy, and was subsequently treated as a carcinoma of unknown primary syndrome case. The final pathologic report showed the evidence of an ectopic breast tissue cancer. Conclusion: Despite the rarity of this condition, physicians should always keep in mind the possibility of ectopic breast cancer in order to make an early diagnosis and adequately treat these patients.
