خلاصه مقاله:

Mental adjustment to cancer is known a psychological, physical and psychological health variable in cancer patients. The present study examined the factor structure and psychometric properties of the Mini - Mental Adjustment to Cancer Scale (Mini-MA) in a sample of Iranian adults. The sample consisted of ۳۲۰ cancer patients selected through non-random convenient sampling procedure from the hospitals and clinics in Kermanshah and Shiraz, and was conducted Mini - Mental Adjustment to Cancer Scale, among of them ۱۰۰ was also completed the Hospital Anxiety and Depression Scale. Statistical methods for analysing the data exploratory, discriminate validity and for internal consistency Cronbach alpha coefficients were used. Alpha coefficients for the subscales helplessness/hopelessness,  $\cdot ۰۹۴$ , cognitive avoidance  $\cdot ۰۷۶$ , anxious preoccupation,  $\cdot ۰۹۰$ , Fatalism,  $\cdot ۰۷۷$ , the fighting spirit  $\cdot ۰۸۰$  and the total scale as well as  $\cdot ۰۸۴$ , respectively. Factor analysis confirmed that the five factors in the Mini-MAC. Significant correlations between subscales of Mini-MAC and Hospital Anxiety and Depression Scale also show that this scale has discriminate validity. The results confirm the five-factor structure of the Mini-MAC scale and also a reliable and valid scale, shows this scale has power to measure aspects of mental adjustment with cancer.
