## خلاصه مقاله:

According to the recent studies, corruption in a society, emanating from the existence of asymmetrical and monopolistic information, is seen as one of the most systematic impediments to economic development. Based on a hypothesis tested in the developed countries, ICT applications, through information dissemination and establishment of e-governments, leads to more transparency and less corruption, though there have been doubts about its effectiveness in reducing corruption in the developing countries. In the present study, the validity of this hypothesis is tested using dynamic panel data method in the Asian developing countries during 2000-2010. The results confirm the links between ICT applications and corruption reduction in the countries of the study. Yet, the results obtained indicate that this relationship is stronger than what previous studies suggested. Also, the study results show the resilient nature of corruption in the selected countries.

## کلمات کلیدی:

ICT applications, Corruption, Dynamic Panel Data, Asian Countries
