خلاصه مقاله:

Background and Aim : Congenital absence of the vagina with variable uterine development known as müllerian agenesis or Mayer-Rokitansky-Kuster-Hauser syndrome. Cervicovaginal agenesis in the presence of normal uterus is very rare. Conservative surgery has recently been suggested in patients with congenital cervicovaginal atresia in order to relieve the symptoms and maintain the fertility capacity. Methods : A 13 year old female referred to pelvic floor clinic, because of primary amenorrhea and severe cyclic pelvic pain. Ultrasonography revealed a large amount of blood accumulation in uterine cavity and also the cervicovaginal agenesis was reported. Both ovaries were normal. A neovagina was created by dissection of the space between bladder and rectum. Under ultrasonography guidance, two Pezzer catheter was inserted between uterine ending and neovagina, so the catheters kept the canal patent, a soft mould was applied to prevent the vaginal stricture. Results : Cervicovaginal agenesis accompanied with normal functional endometrium is a rare but challenging müllerian anomaly in case of surgical treatment. One of the successful conservative treatments in a fully educated patient is vaginal reconstruction and uterovaginal anastomosis by stenting and continuous application of vaginal mould. Conclusion : Cervicovaginal agenesis accompanied with normal functional endometrium is a rare but challenging müllerian anomaly in case of surgical treatment. One of the successful conservative treatments in a fully educated patient is vaginal reconstruction and uterovaginal anastomosis by stenting and continuous application of vaginal mould.

کلمات کلیدی:

vaginal agenesis, conservative treatment, pelvic pain, amenorrhea
